

1) Composing correspondence

In academic and professional settings, I routinely compose clear, audience-appropriate written communication to coordinate work, report progress, and resolve issues. During my research role at Lawrence Berkeley National Laboratory, I communicated with team members to clarify workflow requirements, confirm file locations/transfer procedures, and summarize outcomes from pipeline runs and alignment tasks. I also collaborate cross-functionally in software projects (e.g., coordinating with back-end engineers while developing front-end components), where I write concise messages that document decisions, explain technical constraints, and outline next steps to keep work aligned and moving forward.

2) Accurate record keeping

I consistently maintain organized, accurate records for reproducibility and traceability. At Lawrence Berkeley National Laboratory, I helped improve traceability by developing a structured and searchable data output format that aligned output files directly to experiment-specific input parameters, supporting consistent tracking and future auditing of results. In software development projects, I use version control (Git/GitHub) to maintain accurate change history, document updates through commit messages, and manage branches/merges to preserve a reliable record of work completed and issues resolved.

3) Time/task management

I manage multiple priorities by breaking work into milestones, setting intermediate deadlines, and tracking progress to completion. In fast-paced project environments, I coordinate tasks such as implementing new features, debugging, and testing by sequencing work based on dependencies (e.g., gathering requirements first, then implementation, followed by validation and documentation). In my research and internship roles, I handled tasks that required planning around long-running jobs and deliverables by preparing scripts and workflows in advance, monitoring progress, and documenting outcomes to ensure deadlines and team expectations were met.

4) Use of the following computer programs

a. Word processing

I use word processing tools to produce clear documentation such as technical summaries, project notes, and step-by-step procedures. I write structured documents to explain workflows, record system requirements/specifications, and communicate implementation details so others can reproduce results or maintain software and processes.

b. Spreadsheets

I use spreadsheets to organize and review information such as task tracking, analysis outputs, and project status. For technical work, spreadsheets are useful for sorting/filtering results, tracking

metrics across experiments, and presenting summarized findings for review. I am comfortable structuring tables cleanly and updating them consistently to support accurate reporting.

c. Databases

I have experience working with databases through SQL and tools such as MySQL. In web development coursework/projects, I used SQL to connect and restore tables and improve data organization for reliable retrieval and management. I am comfortable writing queries to validate data, support application functionality, and troubleshoot issues involving stored information.
